

## Types of Bubble Wrap

- 1. High grade bubble wrap:** High grade bubble wrap is known as strong grade and is made with stronger plastics that won't "pop" as easily. This grade should be used when wrapping heavy items, or when there is risk of the item being dropped. The stronger bubbles will help maintain the cushioning.
- 2. General bubble wrap:** General bubble wrap is the most common option and is made with a medium weight plastic that is strong enough to stand up to most typical shipping accidents. The majority of items can be protected from minor damages by using general bubble wrap.
- 3. Low grade bubble wrap:** Low grade bubble wrap generally provides the least amount of protection. It is primarily used to help avoid scratches or other superficial damage during a move. It will not absorb much shock if an item is dropped, shifted or slammed. Do not rely on this type of bubble wrap for padding.
- 4. Anti-static bubble wrap:** Anti-static bubble wrap is made to protect electronic items and is available in any grade. This option should be used when wrapping items like cell phones, computers, or televisions.
- 5. FDA grade bubble wrap:** FDA grade bubble wrap is made for foods that need protection from the shifting and vibrating effects while in transit. It is commonly used when transporting foods like chocolate, fresh fruit, and eggs.
- 6. Temperature controlled bubble wrap:** Temperature controlled bubble wrap is made with a special type of cellular insulation to help maintain the temperature of what is being shipped. This protects the product from extreme temperatures and drastic temperature changes.
